3	—	3	×	1	×	4	—	4	×	2	—	2
4	—	4	—	4	×	1	—	1	—	1	—	1

To get from $1 \dots n$ to $n \dots 1$
 requires

$$N := \binom{n}{2}$$

nearest-neighbour swaps

E.g. $n=4$:

1	2	2	—	2	—	2	3	3	—	3	4
2	1	3	—	3	2	4	3	2	4	3	
3	—	3	1	4	—	4	2	2	—	2	
4	—	4	—	4	1	1	—	1	—	1	

A Sorting Network =

any route from $1 \cdots n$ to $n \cdots 1$
in exactly

$$N := \binom{n}{2}$$

nearest-neighbour swaps

Theorem (Stanley 1984).

$$\# \text{ of } n\text{-particle sorting networks} = \frac{\binom{n}{2}!}{1^{n-1} 3^{n-2} 5^{n-3} \dots (2n-3)^1}$$

Uniform Sorting Network (USN):

choose an n -particle sorting network uniformly at random.

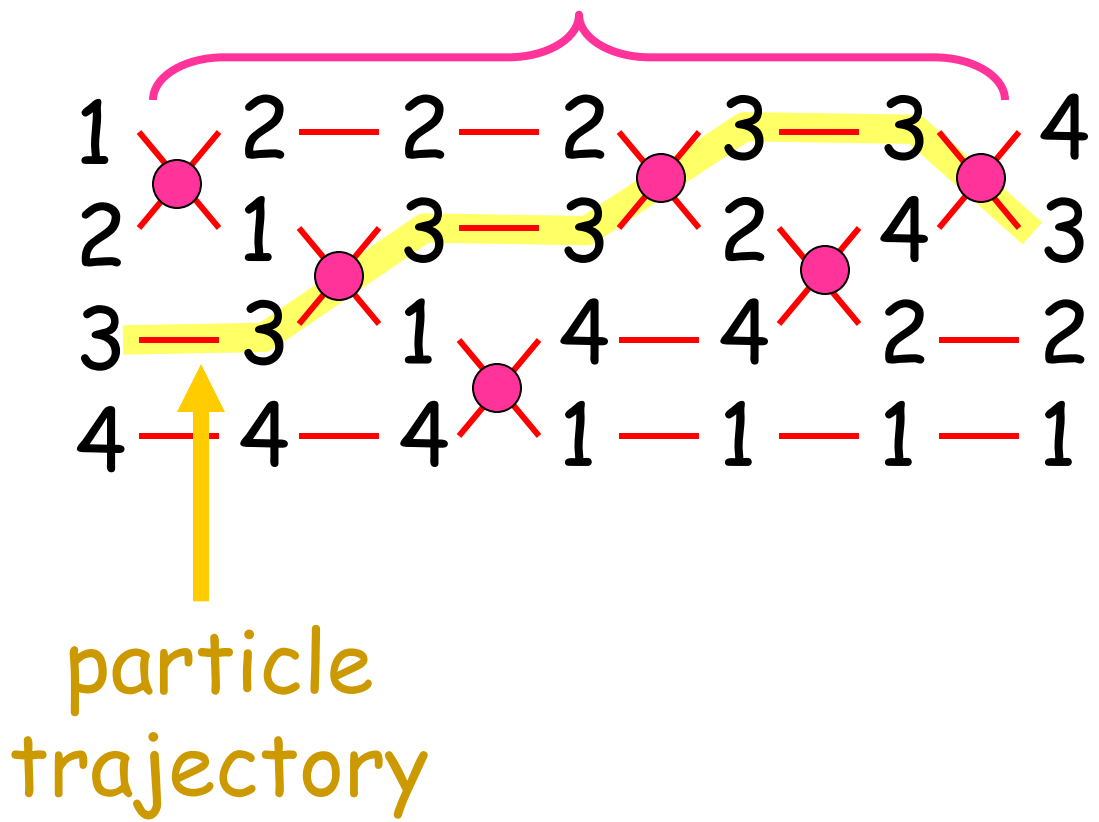

E.g. $n=3$:

$$P\left(\begin{array}{c} \times \text{---} \times \\ \diagdown \quad \diagup \\ \text{---} \times \end{array}\right) = P\left(\begin{array}{c} \text{---} \times \\ \diagdown \quad \diagup \\ \times \text{---} \end{array}\right) = \frac{1}{2}$$

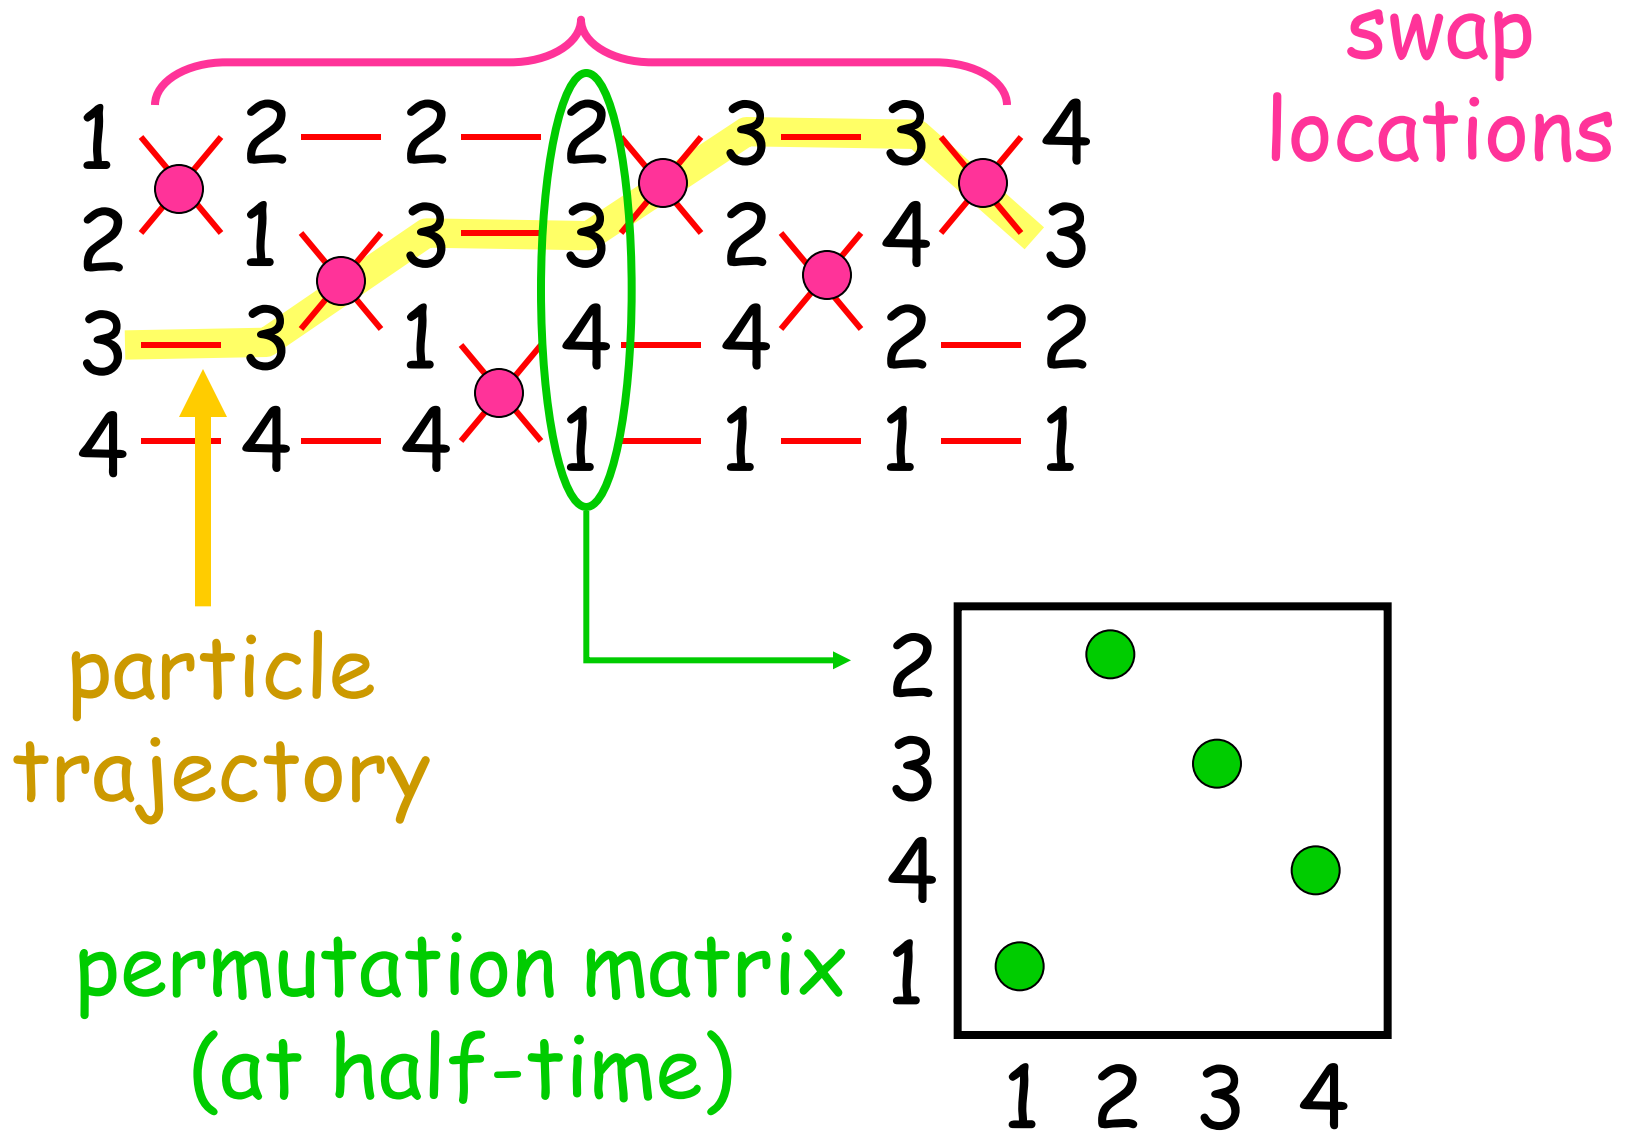

1 ~~X~~ 2 — 2 — 2 ~~X~~ 3 — 3 ~~X~~ 4
2 ~~X~~ 1 ~~X~~ 3 — 3 ~~X~~ 2 ~~X~~ 4 ~~X~~ 3
3 — 3 ~~X~~ 1 ~~X~~ 4 — 4 ~~X~~ 2 — 2
4 — 4 — 4 ~~X~~ 1 — 1 — 1 — 1

swap
locations

swap locations

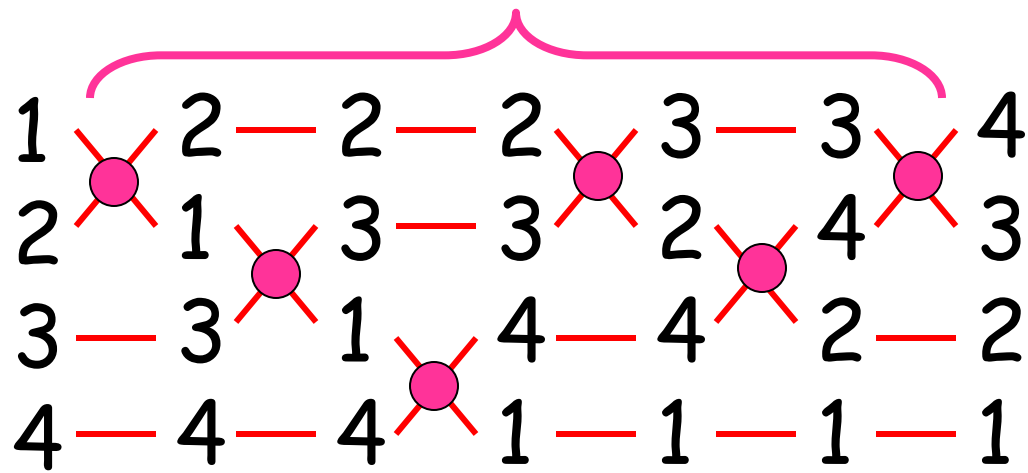

∃ efficient simulation algorithm for USN...

Swap locations, n=100

Swap locations, n=2000

swap
locations

s_1 s_2 s_3 s_4 s_5 s_6
 = = = = = =
 1 2 3 1 2 1

Theorem(Angel,H,Romik,Virag,2007) For USN:

1. Sequence of swap locations

(s_1, \dots, s_N) is stationary

$\forall n$

2. Scaled first swap location

$\frac{s_1}{n} \xrightarrow{\text{dist}}$ semicircle random variable

as $n \rightarrow \infty$

3. Scaled swap process

$\xRightarrow{\text{dist}}$ semicircle \times Lebesgue

as $n \rightarrow \infty$

(Note: not true for *all* sorting networks,
e.g. bubble sort)

Proof of stationarity:

1 ~~X~~ 2 — 2 — 2 ~~X~~ 3 — 3 ~~X~~ 4
2 ~~X~~ 1 ~~X~~ 3 — 3 ~~X~~ 2 ~~X~~ 4 ~~X~~ 3
3 — 3 ~~X~~ 1 ~~X~~ 4 — 4 ~~X~~ 2 — 2
4 — 4 — 4 ~~X~~ 1 — 1 — 1 — 1

Proof of stationarity:

Proof of stationarity:

1 — 1 — 1 × 3 — 3 × 4
2 × 3 — 3 × 1 × 4 × 3
3 × 2 × 4 — 4 × 1 — 1
4 — 4 × 2 — 2 — 2 — 2

Proof of stationarity:

Proof of stationarity:

1 — 1 — 1 × 3 — 3 × 4 — 4
2 × 3 — 3 × 1 × 4 × 3 — 3
3 × 2 × 4 — 4 × 1 — 1 × 2
4 — 4 × 2 — 2 — 2 — 2 × 1

Proof of stationarity:

$(s_1, \dots, s_N) \mapsto (s_2, \dots, s_N, n-s_1)$ is a bijection from {sorting networks} to itself.

So for USN:

$$(s_2, \dots, s_N) \stackrel{d}{=} (s_1, \dots, s_{N-1})$$

Selected trajectories, $n=2000$

Scaled trajectory of particle i :
 $T_i: [0,1] \rightarrow [-1,1]$

Conjecture (AHRV)

trajectories \rightarrow random Sine curves:

$$\max_{i,t} |T_i(t) - A_i^n \sin(\pi t + \Theta_i^n)| \xrightarrow{Prob} 0$$

(random)

as $n \rightarrow \infty$

Theorem (AHRV)

scaled trajectories have subsequential limits which are Hölder($\frac{1}{2}$) with prob 1

as $n \rightarrow \infty$

Half-time permutation matrix, $n=2000$

animation

Conjecture (AHRV)

scaled permutation matrix at time $N/2 \xRightarrow{d}$ Archimedes measure

projection of surface area measure on sphere $S^2 \subset \mathbb{R}^3$ onto \mathbb{R}^2

(unique circularly symmetric measure with uniform linear projections;

$$\frac{dx dy}{2\pi \sqrt{1 - x^2 - y^2}} \text{ on } x^2 + y^2 < 1$$

scaled permutation matrix at time $tN \xRightarrow{d} \begin{pmatrix} 1 & 0 \\ \cos \pi t & \sin \pi t \end{pmatrix} \circ \text{Arch. meas.}$

Theorem (AHRV)

scaled permutation matrix at time tN
is supported within a certain octagon
with prob $\rightarrow 1$

as $n \rightarrow \infty$

$$(1 - \frac{1}{2}\sqrt{3 - \varepsilon})n$$

Tools in proofs:

1. Bijection (Edelman-Greene 1987)

{sorting networks} \leftrightarrow {standard staircase
Young tableaux}

(jeu de taquin
algorithm)

1	2	4	8
3	5	6	
7	10		
9			

2. New result for limiting profile of random staircase Young tableau

(from similar result for
square tableaux,
Pittel-Romik)

Why do we believe the conjectures?

The permutahedron:

embedding of Cayley graph
(S_n , n.n. swaps) in \mathbb{R}^n :

$$\sigma \mapsto \sigma^{-1} = (\sigma^{-1}(1), \dots, \sigma^{-1}(n)) \in \mathbb{R}^n$$

$n=4$:

embeds in
($n-2$)-sphere

1... n and n ...1
are antipodal

$n=5$

Conjecture (AHRV)

USN lies **close** to some **great circle** on the permutahedron **with prob $\rightarrow 1$**

as $n \rightarrow \infty$

e.g. $o(n)$ in l_1 l_∞

In fact simulations suggest more like $O(\sqrt{n})$!

(Again, not true for *every* sorting network, e.g. bubble sort)

Theorem (AHRV) If a (non-random) sorting network lies close to some great circle, then:
($o(n)$ in l_∞)

1. Trajectories \approx Sine curves

2. Half-time permutation \approx Archimedes measure

3. Swap process \approx semicircle \times Lebesgue

Simulation

Proof of Theorem:

close to great circle \Rightarrow

\approx Sine trajectories (up to a time change)

$\Leftrightarrow \approx$ rotating disc picture

projections uniform $\Rightarrow \approx$ Archimedes

swap rate uniform \Rightarrow rotation uniform

\Rightarrow no time change

calculation \Rightarrow semicircle law

Geometric Sorting Networks

Geometric Sorting Networks

Geometric Sorting Networks

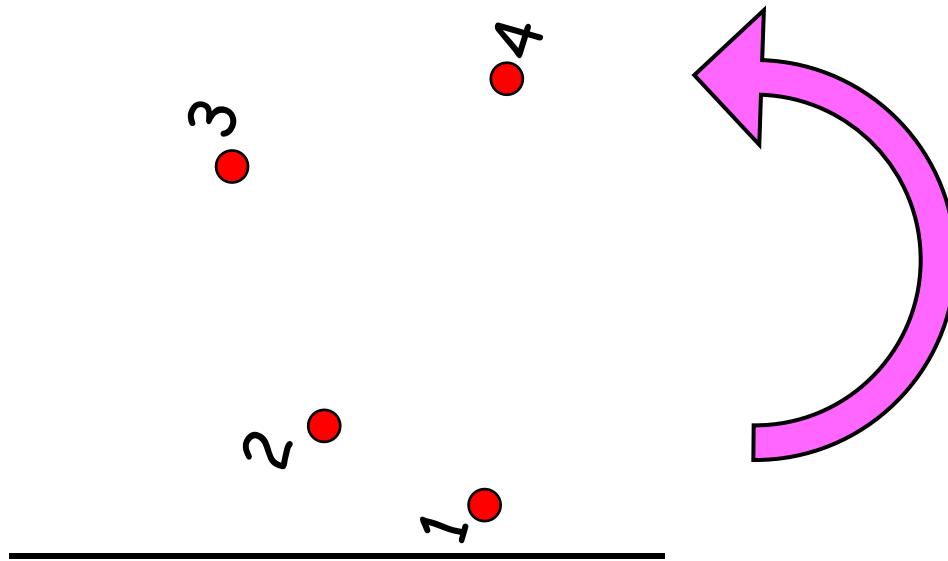

Geometric Sorting Networks

Geometric Sorting Networks

Geometric Sorting Networks

Geometric Sorting Networks

Goodman, Pollack (1980):

- all 4-item sorting networks are geometric
- but not all 5-item ones:

Goodman, Pollack (1980):

- all 4-item sorting networks are geometric
- but not all 5-item ones:

Great circle conjecture says:

USN is " \approx geometric" as $n \rightarrow \infty$

but:

Theorem (Angel, H, Gorin, in prep)

$P(\text{USN is geometric}) \rightarrow 0$ as $n \rightarrow \infty$

Proof: in fact:

$P(\text{USN contains fixed swap pattern}) > 1 - e^{-cn}$

e.g. Goodman-Pollack counterexample

Subnetworks

Subnetworks

Subnetworks

Subnetworks

Random Subnetworks

Take an n -item USN. Choose m out of the n items uniformly at random, indep. of USN.

Great circle conjecture \Rightarrow

m fixed, $n \rightarrow \infty$:

random
 m -out-of- n network

geom. network of
 m indep. points from
Archimedes distn.

Conjecture (Warrington, 2009)

$$P \left(\begin{array}{l} \text{random} \\ \text{4-out-of-}n \\ \text{network} \end{array} \in \begin{array}{l} \{\text{geom. networks} \\ \text{with 1 point in} \\ \text{hull(other 3)}\} \end{array} \right) = \frac{1}{4}$$

for all n !

Theorem (Angel, H 2009)

Warrington's conjecture is true.

Moreover, $\forall j < m \leq n$,

$E(\text{\# swaps in location } j \text{ in } m\text{-out-of-}n \text{ random network})$

does not depend on n

$$\text{and} = \frac{(j - \frac{1}{2}) \cdots \frac{753}{222} \times (m - j - \frac{1}{2}) \cdots \frac{753}{222}}{(j - 1)! \times (m - j - 1)!}$$

consistent with Archimedes distribution conjecture about $n \rightarrow \infty$ limit

Ingredients of proof

$P(s_1=k) = P(k-1 \text{ white balls added in first } n-2 \text{ in Polya urn})$

↑
1st swap location
in USN

initially
 $1\frac{1}{2}W, 1\frac{1}{2}B$

Stationarity of USN

Exchangeability of Polya urn $P(wwwbb) = P(wbwbw)$

Compute

$P(\text{given space-time point in USN})$

\Rightarrow swap at location j
in subnetwork)

Uniform swap model...

Angel, H, Romik 2008

Amir, Angel, Valko

...

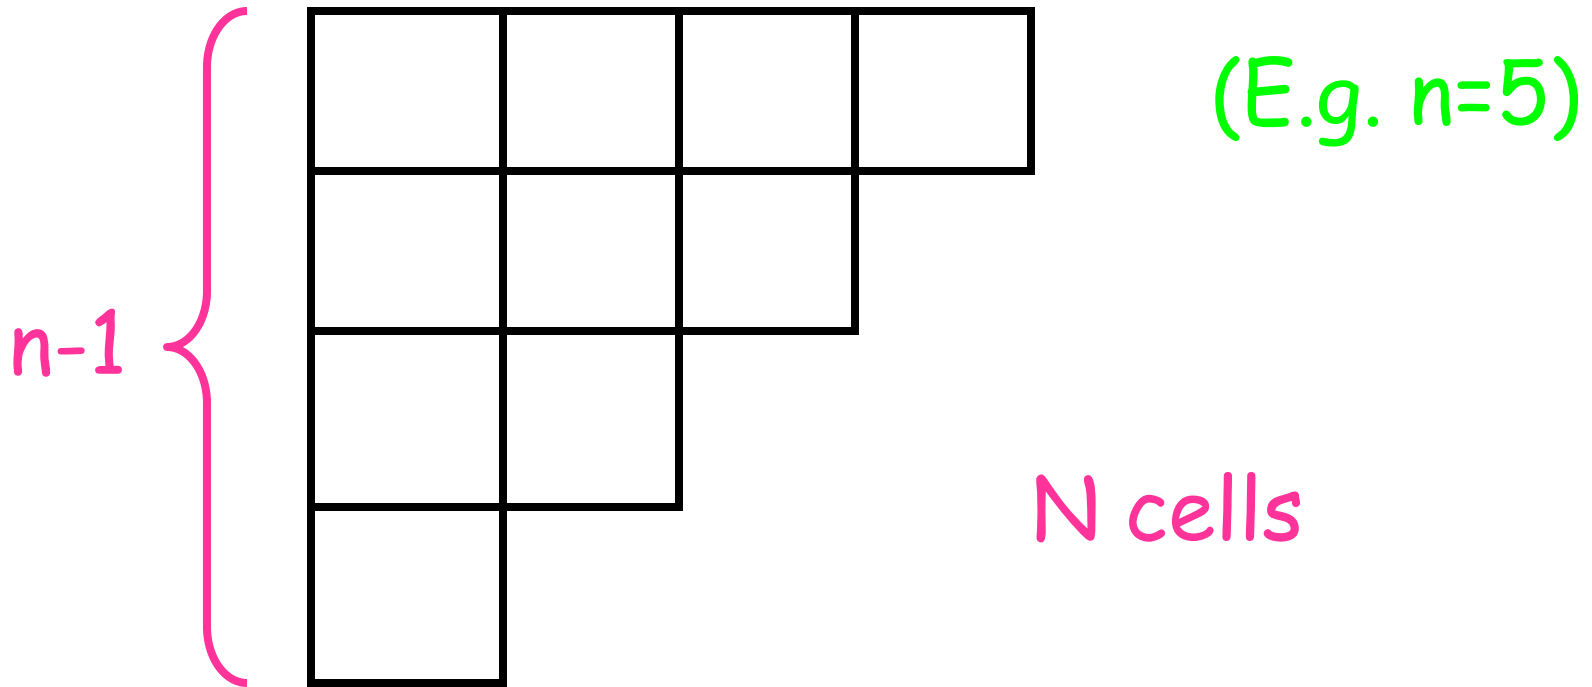

N.B. Not every sorting network lies close to a great circle! E.g. typical network through

(But this permutation is very unlikely).

Staircase Young diagram:

Standard staircase Young tableau:

1	2	4	8
3	5	6	
7	10

Edelman-Greene algorithm:

Edelman-Greene algorithm:

etc

Edelman-Greene Theorem:

After N steps,

Edelman-Greene Theorem:

After N steps,
get swap process
of a sorting network!

1	1	1	1	4	4	4	4	5	5	5
2	2	4	4	1	1	5	5	4	4	4
3	4	2	2	2	5	1	2	2	2	3
4	3	3	5	5	2	2	1	1	3	2
5	5	5	3	3	3	3	3	3	1	1

Edelman-Greene Theorem:

After N steps,
get swap process
of a sorting network

And this is a bijection!

And can explicitly describe inverse!

Theorem (Pittet-Romik): For a uniform random $n \times n$ square tableau, \exists limiting shape with contours:

$$h_\alpha(u) = \frac{2}{\pi} [u \tan^{-1}(u/R) + \tan^{-1} R]$$

$$\text{where } R = \frac{\sqrt{\alpha(2-\alpha) - u^2}}{1-\alpha}$$

Corollary (AHRV): For uniform random staircase tableau, limiting shape is half of this.

(Proof uses Greene-Nijenhuis-Wilf Hook Walk)

Proof of LLN (swap process \Rightarrow semic. \times Leb.)

Swaps in space-time window $[a_n, b_n] \times [0, \varepsilon N]$
come from entries $> (1-\varepsilon)N$ in tableau:

\approx area under contour \approx semicircle

Proof of octagon and Holder bounds

Inverse Edelman-Greene bijection
(\approx RSK algorithm) \Rightarrow

entries $< k$ in 1st row

\geq longest \nearrow subseq. of swaps
by time k

\geq furthest any particle moves up
by time k

So can bound this using
limit shape.

Angel, H, Virag (in preparation):

Process of first k swaps
in positions $cn \dots cn+k$

→ random limit

as $n \rightarrow \infty$

not depending on $c \in (0,1)$
